If the two genes are different, then there is a question as to which of them will determine how the animal actually looks or functions. The defective G-6-S mutation is a simple recessive gene, which means that a goat which has only one copy of it will appear perfectly normal and will not show any of the symptoms described above.

The GNA11 gene provides instructions for making one component, the alpha (α) subunit, of a protein complex called a guanine nucleotide-binding protein (G protein). Each G protein is composed of three proteins called the alpha, beta, and gamma subunits. Specifically, the protein produced from the GNA11 gene, called Gα 11, is the alpha subunit for a G protein called G 11.

Virtually any known gene can be expressed in cells and its function studied. Once the sequence of a gene is known the gene can be amplified with PCR or by growing it in bacteria. The gene can then be linked to a promoter and placed into a circular piece of DNA, which is then placed into cells by a variety of methods.
