The family Rhabdoviridae currently has 18 genera accepted by the International Committee for Virus Taxonomy (ICTV), and three of those genera contain fish rhabdoviruses. In the genera Novirhabdovirus, Sprivivirus, and Perhabdovirus all viruses infect fish hosts, and there are no fish viruses in any of the other 15 rhabdovirus genera.

Rhabdoviruses are negative, ss, monopartite RNA viruses. They are noninfectious because their negative sense RNA genome cannot be immediately translated upon entry into the cell. They do not have a 5' cap or a polyA tail. Their capsid is roughly bullet shaped and about 75 nm wide and 180 nm long.

### **RHABDOVIRIDAE**

Enveloped, bullet shaped. 180 nm long and 75 nm wide. Certain plant rhabdoviruses are bacilliform in shape and almost twice the length. GENOME. Negative-stranded RNA linear genome, about 11-15 kb in size. Varicosavirus genomes consists in two segments. Encodes for 5 to six proteins. GENE EXPRESSION

Plant rhabdoviruses are transmitted by aphid, leafhopper or planthopper vectors, and the viruses replicate in both their insect and plant hosts. The two plant rhabdovirus genera, Nucleorhabdovirus and Cytorhabdovirus, can be distinguished on the basis of their intracellular site of morphogenesis in plant cells.
